**INTRODUCTION**

The outbreak of coronavirus disease in late 2019 is far more than a global crises. COVID-19 has had a serious impact on all parts of our society. The ongoing COVID-19 pandemic has already turned healthy places around the world into a living hell with massive death tolls because of its fastest spreading nature, and continuously leading to lockdowns in almost every part of the world [1].

Health care is one of the basic needs of each community. Since considering to healthcare and investing in this sector increases labor productivity and service production, therefore, optimal resource allocation and use of resources is very important [2].

Evaluation of health care programs can determine their quality and progress of implementation and failure or success rate [2]. Hospital services absorb almost half of health sector costs, so efficiency promotion of these services through cost reduction and use of potential capacity of health care organizations is necessary [4].

Diverse economic incentives have been used for cost reduction in hospitals. However, in the field of patient access to hospital services and the quality of services have not yielded to positive results. For preserving quality and accessibility, it is necessary to focus on cost containment indexes by attention to the appropriateness or inappropriateness of health care services [5]. Some cost containment strategies such as reduction in hospital beds have increased hospital waiting time. To overcome this problem, we should use hospital beds at highest efficiency and the best way for efficient use of hospital beds is to avoid or to minimize inappropriate patient hospitalization and not to decrease the quality [6].

The study of profile of patients attending respiratory clinic/COVID clinic will allow appropriate utilization of scarce resources and hence this study was carried out to help to help against this pandemic.

**AIMS AND OBJECTIVES**

To study the profile of the patients attending the respiratory clinic during second COVID 19 wave.
MATERIAL AND METHODS

Study Design and Duration
A retrospective study for a period of three months from 1st January 2021 to 31st March 2021 was carried out to know the socio-demographic profile of patients attending the respiratory clinic.

Sampling
The patients attending respiratory clinics during pandemic were included.

Study Tool
A pretested and predesigned Proforma was used to record information from the patient’s records about each case admitted to study demographic data.

Statistical Analysis
The data was entered in MS excel. Descriptive analysis was done to calculate proportions.

RESULTS AND OBSERVATIONS
A total of 2000 patients were studied for the profile.

Age-Wise Distribution of Patients
A total of 2000 patients were studied, out of which 40.0% (n=800) of the patients belonged to the age group of 41-60 followed by 30.0% (n=600) of the patients in >60 age group. Only 10.0 % (n=200) belonged to the age group of <20 (Table 1).

Presenting Symptoms
Out of 2000 patients studied, majority of the patients presented with cough and fever.

Gender-Wise Distribution of Patients
Out of 2000 cases studied during the study period, 63.0% (n=1260) were males and 37.0% (n=740) were females (Figure 1).

Geographical Distribution of Patients
In our study, majority of the patients 75.0 % (n=1500) patients were from rural area and only 25.0% (n=500) from urban area (Figure 2).

Marital Status
In our study, 75.0% (n=1500) of the study population were married and 25.0% (n=500) were unmarried (Figure 3).
Duration of Symptoms

In our study, out of 2000 patients, majority of the patients 63.0% (n=1260) had length of symptoms >3 days followed by 22.0% (n= 440) had length of symptoms 2-3 days, only 15.0% (n=300) of the patients had length of symptoms 0-1 day (Figure 4).

Referrals

Only 16.0% (n=320) of the cases were referrals out of 2000 cases studied (Figure 5).

DISCUSSION

A 200 patients were followed retrospectively for studying the profile. Apolone G et al [7] observed that 57.0% of the patients were in the age group of > 60 years. In our study, majority of the patients (40.0%) belonged to the age group of more than 41-60 years. Apolone G et al [7] observed that 58.0% of the patients were males observed. In our study, majority of the admissions were of the males (63.0%). These findings are consistent with our study. Hwang JI et al [8] conducted a study on hospital stay and observed that 53.5% of the patients were from rural areas. In our study, majority of the patients were from rural areas (75.0%). Tawakoli N et al [9] conducted a study on hospital stay and observed that 54.5% patients were married. In our study, maximum of the study population was married (75.0%). In line with the finding of our study, Apolone G et al [7] showed that 90.0% of the patients had length of stay > 3days while as Tawakoli N et al [9] showed that 60.0% of cases had length of stay > 3days. In our retrospective part, out of 2000 patients, majority of the patients (63.0%) had length of stay > 3days.

CONCLUSION

Health care is one of the basic needs of each community. Since considering to healthcare and investing in this sector increases labor productivity and service production, therefore, optimal resource allocation and use of resources is very important. It was found during the study that majority of the patients were more than 41-60 years of age (40.0%), cough was chief complaint (80.0%). Majority of the Admissions were Direct and only 16 % of cases were referrals.

Conflict of interest: None

Source of funding: None

Ethical clearance: Taken
